

Six-Week Mindfulness Training and Perceived Stress: A Pilot Study

Huang et al.

2022

Abstract

This pilot study tested a six-week mindfulness training program in university students. Forty-two participants completed weekly group sessions and daily home practice.

Methods

The mean PSS-10 perceived stress score decreased from 22.0 at baseline to 18.0 after six weeks, representing an 18 percent reduction. The study did not include 500 participants. The study did not measure salivary cortisol, sleep efficiency, vocabulary recall, or academic grades.

Conclusion

Mindfulness training was associated with a modest reduction in perceived stress in a small pilot sample. Larger trials are needed before making broad claims about academic performance.
